#### Introduction

## High Performance Computing

Numerical simulations used in many scientific fields

- Biology,
- Physics,
- Cosmology,
- Chemestry,
- Industrial & Academics
- Complexity of the problem, Massively Parallel

R

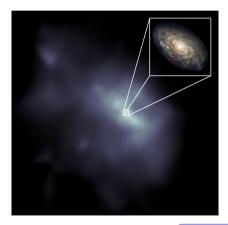

Figure: Dark matter halo image (Credit: CPAC group, ANL)

#### Introduction

## Supercomputers: large-scale machines

- Hierarchical layout
- Computing power: growth factor of 220 in last 10 years
- "Fugaku"
  - Equivalent to 1.5 million laptops
  - Energy consumption of  $\sim$  22.000 households

8

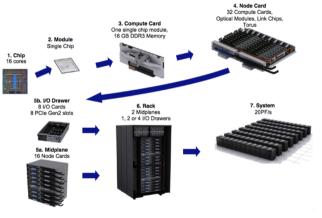

Figure: Structure of supercomputers: interconnected hierarchical boxes Source

Introduction

### Emergence of New Workloads

- Arise from Machine Learning and BigData
- Deep Learning as a major tool
  - Major interest in Artificial Intelligence
  - Neural Networks as the reference tool
- Progress: Larger datasets
- Consequence: compute-intensivity

8

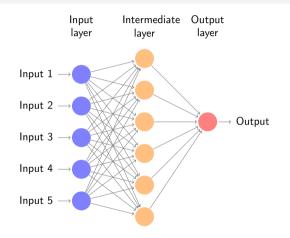

Figure: Illustration of neural network structure

## Outline

#### 1 Issue in Question

### Running Applications on Supercomputers

### Typical Scientific Applications

- Models of real-life phenomenon
- Complex code with high degree of parallelism
- Output: huge amount of data (datasets in PetaBytes)
- Hardware Limitations: limited size of PFS + access bandwidth
  - PFS capacity growth factor: 25 (2010-2020)\*
  - Bandwidth growth factor:  $< 2 (2010-2020)^*$
- Software Limitations: Reaching perfect parallelism
  - Inherent sequential parts in applications
  - Amdahl's law, Gustafson law, etc

### Recently: new applications on supercomputers

- Convergence HPC/BigData-ML
- Our focus: the new applications
- Neurosciences, Computational Biology
- $\bullet$  Applications: different models  $\rightarrow$  different needs
- Machine: different users  $\rightarrow$  different behavior

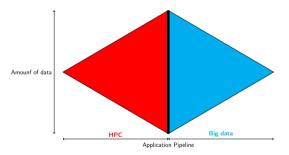

Figure: Convergence between HPC and BigData

#### ssue in Question

#### 2 Reservation Strategies for Stochastic Jobs

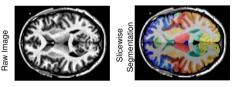

Operation of the second sec

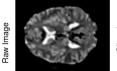

HPC-Big Data Convergence: Managing the Diversity of Application Profiles on HPC Facilities Reservation Strategies for Stochastic Jobs Case Study: High Level Observations

### SLANT, a representative Neuroscience application

- High-resolution whole brain segmentation from MRI pictures
- Dynamic code, multiple stages, predictable memory requirement
- Execution of CPU version, 2 datasets: DRD and OASIS
- Platform: Haswell on Plafrim

(a) Segmentation for OASIS.

Slicewise Segmentatio

(b) Segmentation for DRD.

Figure: Typical inputs and outputs based on the dataset.

**Reservation Strategies for Stochastic Jobs** 

Case Study: High Level Observations

### High-level observations: walltime profile

- Variations are confirmed
- Where does these variations come?
- Can we predict it?
- Run-to-run variability? 🗡

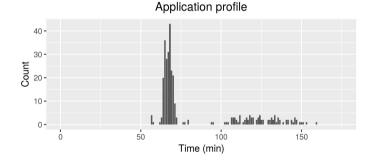

Figure: SLANT application walltime variation for various inputs.

15

**Reservation Strategies for Stochastic Jobs** 

Case Study: High Level Observations

#### High-level observations: walltime prediction?

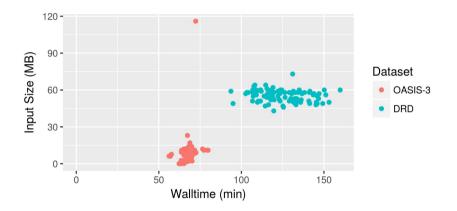

Figure: Correlation between the size of the input and the walltime over the 312 runs.

**Reservation Strategies for Stochastic Jobs** 

Case Study: High Level Observations

#### High-level observations: walltime prediction?

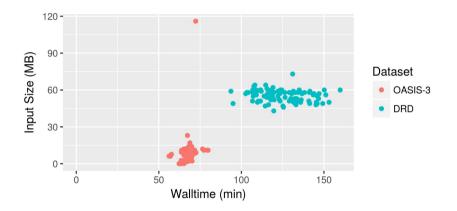

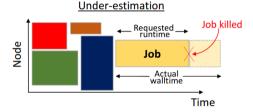

Figure: Correlation between the size of the input and the walltime over the 312 runs.

# Let us accept this variation, in what is it a problem in HPC?

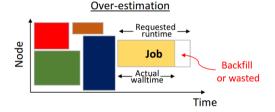

**Reservation Strategies for Stochastic Jobs** 

Case Study: High Level Observations

## Difficulty of unknow execution time in HPC<sup>†</sup>

- Killed job + resubmission = low performance
- Waste of system resources

- Early termination, possible waiting time in scheduler queue
- Backfilling

#### Importance of accurate prediction of application walltime

#### <sup>†</sup>Credit pictures: Hongyang SUN

HPC-Big Data Convergence: Managing the Diversity of Application Profiles on HPC Facilities Reservation Strategies for Stochastic Jobs Case Study: High Level Observations

#### Overall high-level observations

- Significant variations in the walltime
- Variations determined by elements from the input
- Variations not correlated to the size of the input (quality and not quantity)
- Approach: successive reservations until job terminates

#### Reservation strategies for stochastic jobs

#### We provide

- Model(s) of the applications
- Odel(s) of the platforms
- An optimization problem.

#### Reservation-based Approach

Given a job J of duration t (unknown). The user makes a reservation of time  $t_1$ . Two cases:

- $\mathbf{t} \leq t_1$  The reservation is enough and the job succeeds.
- $\mathbf{t} > t_1$  The reservation is not enough. The job fails. The user needs to ask for another reservation  $t_2 > t_1$ .

**Drawback:** Failed reservations = Lost of the job progress = Waste of resources

Solution: introduce checkpoint at the end of (some) well-chosen reservations

- Assume flat memory model
- C: fixed checkpoint overhead
- R: restart overhead

Reservation Strategies for Stochastic Jobs

An illustrative example

## Motivational example (1/2)

Job execution time follows a Random Variable X.

- $\bullet$  Distribution  ${\cal D}$
- Cumulative function (CDF), Density function (PDF)
- Support is positive  $(X \in [\min_{\mathcal{D}}, \max_{\mathcal{D}}], \text{ s.t.} \min_{\mathcal{D}} \ge 0 \text{ and } \max_{\mathcal{D}} \in \mathbb{R} \cup \{\infty\})$
- Let  $X \sim \text{LogNormal}(21.4, 19.7)$  on [0, 80]

Platform

- Cost = cost of reservations
- C = R = 7

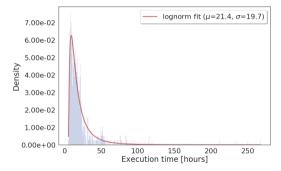

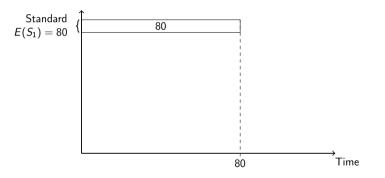

Figure: Execution times from 2017 for a *Structural identification of orbital anatomy* application, and its fitted distribution (in red).

Reservation Strategies for Stochastic Jobs

An illustrative example

### Checkpointing: Motivational example (2/2)

•  $S_1$  (Standard):  $t_1 = 80$ 

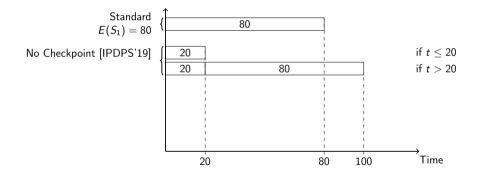

Reservation Strategies for Stochastic Jobs

An illustrative example

### Checkpointing: Motivational example (2/2)

•  $S_2$  (No Checkpoint):  $t_1 = 20$ ,  $t_2 = 80$ 

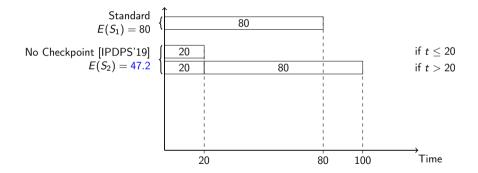

Reservation Strategies for Stochastic Jobs

An illustrative example

### Checkpointing: Motivational example (2/2)

• 
$$\mathbb{E}(S_2) = 20 \cdot \mathbb{P}(X \le 20) + (80 + 20) \cdot \mathbb{P}(20 < X \le 80) = 47.2$$

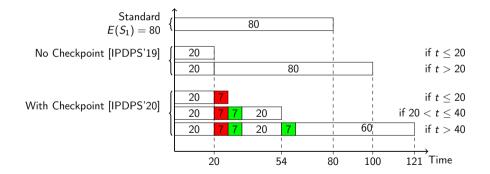

HPC-Big Data Convergence: Managing the Diversity of Application Profiles on HPC Facilities Reservation Strategies for Stochastic Jobs

An illustrative example

#### Checkpointing: Motivational example (2/2)

•  $S_3$  (With Checkpoint):  $t_1^C = 20 + C$ ,  $t_2^R = R + 20$ ,  $t_3^R = R + 60$ 

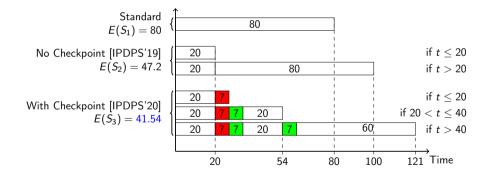

**Reservation Strategies for Stochastic Jobs** 

An illustrative example

#### Checkpointing: Motivational example (2/2)

•  $\mathbb{E}(S_3) = 27 \cdot \mathbb{P}(X \le 20) + (27 + 27) \cdot \mathbb{P}(20 < X \le 40) + (54 + 67) \cdot \mathbb{P}(40 < X) = 41.54$ 

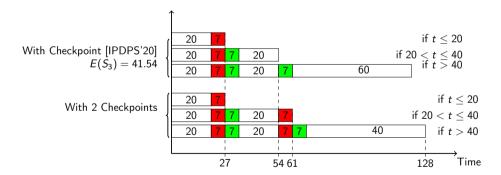

Reservation Strategies for Stochastic Jobs

An illustrative example

#### Checkpointing: Motivational example (2/2)

•  $\tilde{S}_3$  (With 2 Checkpoints):  $t_1^C = 20 + C$ ,  $\tilde{t}_2^{R,C} = R + 20 + C$ ,  $t_3^R = R + 60$ 

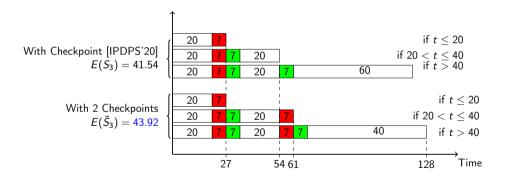

**Reservation Strategies for Stochastic Jobs** 

An illustrative example

#### Checkpointing: Motivational example (2/2)

•  $\mathbb{E}(\tilde{S}_3) = 27 \times 0.66 + 61 \times 0.26 + 128 \times 0.08 = 43.92 > \mathbb{E}(S_3)$ 

#### Complexity of checkpointing decision

**Reservation Strategies for Stochastic Jobs** 

Algorithmic contributions

## Algorithmic contributions for stochastic jobs

- Checkpointing not always available
- Solutions for both application models

No checkpoints

\* Determine a sequence of reservations

With checkpoints:

- $\star$  Determine the size of reservations
- \* Associate checkpointing decision to each reservation

A First Memory-aware Heuristic

# Conclusion on stochastic applications

- Variation in execution time
- Sequence of reservations
  - Checkpoints to save application progress
  - Various algorithmic contributions
- Different performance evaluation
  - Simulations on synthetic applications
  - Experiments on real data and application
- Profiling applications for better strategies
  - Memory profiling to improve checkpointing strategy

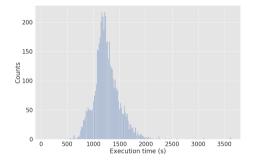

Figure: Traces [2013-2016] of VBMQA application (Vanderbilt's medical imaging database).

#### Conclusion

## Table of Contents

2 Reservation Strategies for Stochastic Jobs

Operation of the second sec

Conclusion

Summary of Contributions

# Contributions to application management in HPC

- HPC/BigData-ML convergence
- Categorizing applications
- Derived strategies for each category
  - Expressed models for both platforms and applications
  - Derive scheduling heuristics and/or resource partitioning strategies
  - Extensive set of simulations and experiments
- Importance of application knowledge
  - Critical for performance of our strategies
  - Using profiling to better understand needs
  - From first solutions to practical ones

Conclusion

Perspectives

### Short term perspectives

- Continue theoretical contributions
- Include system constraints in model
  - Contention
  - Checkpoint not only at the end of reservation
  - Application-aware checkpointing
- Integration in frameworks

Conclusion

Perspectives

### Global perspectives

- Theoretical models, practical?
  - Convince users to use models
  - "Scheduler, where are you?"
- Study of users and application behavior at scale
- From static to dynamic decisions
  - Benefits of feedback during execution
  - Frequency of model revaluation
  - "dynamic" reservations

Conclusion

Perspectives

# Thank you for your attention!

Conclusion

#### Perspectives

#### Context: Computing in the cloud

Several cost models to compute in the cloud:

• **On-Demand (OD):** "you pay for compute capacity by per hour or per second depending on which instances you run" (Amazon AWS).

(= Pay what you use)

• **Reserved-Instances (RI):** "Reserved Instances provide you with a significant discount (up to 75%) compared to On-Demand instance pricing."

(= Pay what you ask for)

Payment Option	Upfront	Monthly*	Effective Hourly**	Savings over On-Demand	On-Demand Hourly
No Upfront	\$0	\$8.03	\$0.011	57%	
Partial Upfront	\$134	\$3.72	\$0.010	60%	\$0.0255
All Upfront	\$252	\$0.00	\$0.010	62%	

Figure: Data extracted from AWS website, 12/10/2018.

#### Conclusion

#### Perspectives

### Context: Computing in HPC

#### Total time = Wait time + Runtime:

Conclusion

From simulation to experiments

#### From simulation to experiments

• Scheduling multiple jobs in an HPC environment

Conclusion

From simulation to experiments

#### From simulation to experiments

- Scheduling multiple jobs in an HPC environment
- 3 different applications

Application Type	Walltime distribution	С	R
Diffusion model fitting (Qball)	Gamma $(k = 1.18, \theta = 34, [a, b] = [146s, 407s])$	90s	40s
Diffusion model fitting (SD)	Weibull ( $k = 1043811$ , $\lambda = 1174322466$ , [ $a, b$ ] = [ $46min, 2.3h$ ])	25min	10min
Functional connectivity analysis (FCA)	Gamma ( $k = 3.6, \theta = 72,$ [ $a, b$ ] = [165 $s$ , 1003 $s$ ])	150s	100s

Table: Characteristics of the chosen neuroscience applications.

Conclusion

From simulation to experiments

#### From simulation to experiments

- Scheduling multiple jobs in an HPC environment
- 3 different applications
- Two different sets of strategies
  - **(**) "HPC-for-neuroscience strategy" (HPC): average of 5 last runs then  $\times 1.5$
  - Our Dyn-Prog-Count strategy + All-Checkpoint variant

Conclusion

From simulation to experiments

### From simulation to experiments

### Setup

- 256-thread Intel Processor Xeon Phi 7230, 1.30GHz
- Record application completion time, for 500 runs of each application
- Metrics for system performance:
  - stretch: total execution time / actual walltime
  - 2 utilization: sum of all jobs' walltimes / total time required to execute them

Conclusion

From simulation to experiments

# Experiments: performance of strategies

- 500 jobs of each applications are submitted
- C/R manually forced to be as presented in previous table (study of application interference and runtime variability)

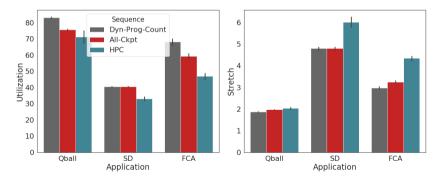

Figure: Utilization and average job stretch for Dyn-Prog-Count, All-Checkpoint and the HPC strategies.

#### Conclusion

From simulation to experiments

## Experiments: what if C/R vary?

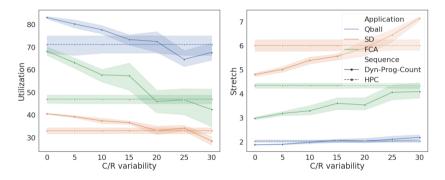

Figure: Utilization and average job stretch for the three applications (blue: Qball; Orange: SD; Green: FCA) when varying the C/R costs by different percentages (0 to 30%) using the Dyn-Prog-Count strategy. Horizontal lines represent the results for the HPC strategy.

•

Conclusion

From simulation to experiments

e

# Experiments: what about application interference?

- Running all three applications at same time
- 500 jobs (100 from Qball, and 200 each from SD and FCA)
- C/R costs constant across different reservations
- HPC strategy: 10 different runs choosing 10 different instances from traces

Conclusion

From simulation to experiments

# Experiments: what about application interference?

Table: Utilization and average job stretch for 10 different runs, each using 500 jobs from all three applications. The runs are ordered by the best improvement of Dyn-Prog-Count in utilization.

Dyn-Prog-Count		HPC		Improvement	
Utilization	Avg Stretch	Utilization	Avg Stretch	Utilization	Avg Stretch
67	2.04	55	2.34	21%	15%
73	1.72	62	2.04	18%	19%
62	2.08	55	2.46	12%	18%
71	1.88	64	2.1	11%	12%
63	2.19	56	2.41	11%	10%
71	1.74	64	1.96	10%	12%
75	1.51	68	1.69	10%	12%
68	2.09	65	2.19	4%	5%
61	2.24	60	2.32	2%	4%
77	1.96	75	1.99	2%	2%

#### Conclusion

From simulation to experiments

# Mem-All-Ckpt heuristic

• "likely" maximum memory needed as a function of time

$$M_{ au}(t) = \max\left\{M_i | \mathbb{P}\left(\sum_{j < i} X_i < t \le \sum_{j \le i} X_i
ight) > au
ight\}$$
 (1)

• 
$$Y \sim (v_i, C_i, f_i)_{1 \leq i \leq n}$$
, s.t. for  $1 \leq i \leq n$ ,  $\mathbb{P}(Y = v_i) = f_i$ 

• Dynamic-programming algorithm

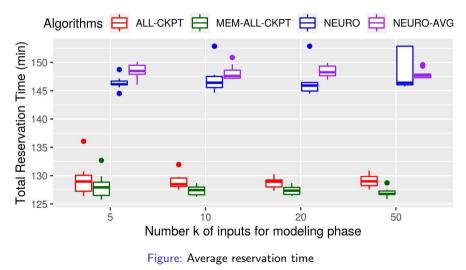

$$\begin{cases} S_{\text{MAC}}(n) = 0\\ S_{\text{MAC}}(i) = \min_{i+1 \le j \le n} \left( S_{\text{MAC}}(j) + (R + (v_j - v_i) + C_i) \cdot \sum_{k=i+1}^n f_k \right) \end{cases}$$

- Checkpoint cost C<sub>i</sub>
  - All-Checkpoint: Max. memory peak of application
  - Mem-All-Ckpt:  $M_{\tau}(v_i)$ 
    - .

Conclusion

From simulation to experiments

# A first step for memory-aware algorithms

Conclusion

From simulation to experiments

e

## A "second" step for memory-aware algorithms

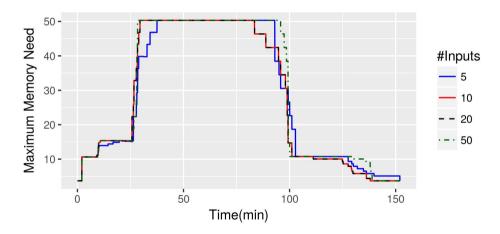

Figure: Interpolation of peak memory over time.

Conclusion

From simulation to experiments

## A "second" step for memory-aware algorithms

- Mem-All-Ckpt: first reservation of >100min
- $R_1$ : memory peak of 50GB
- Enhancement: checkpoint just before task 5 (<25min)
- Mem-All-Ckptv2

Conclusion

From simulation to experiments

# A "second" step for memory-aware algorithms

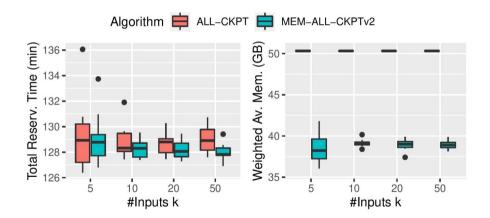

Figure: Average reservation time

Conclusion

From simulation to experiments

# Usual speedup laws

Amdahl's law  

$$S = \frac{1}{(1-p) + \frac{p}{s}}$$
(2)

- S = speedup
- *p* = fraction of code that benefits
- s = speedup of fraction p

Difference: Amdahl assumes fixed problem size

### Gustafson's law

$$S = N + (1 - N) \times s \tag{3}$$

- *S* = speedup
- *N* = processors
- s = sequential fraction

### Conclusion

From simulation to experiments

# Covid-friendly buffet!!!
